Foreword

This guide helps officials use perception surveys to evaluate and communicate the results of reform processes. While the guide draws on examples from the regulatory field, it is also useful for other policy areas. In non-technical language, the guide clearly explains the challenges involved in the design and use of business and citizen perception surveys – and ways to overcome them. It also helps officials get the most out of survey results, whether conducted internally or by external experts.

This guide is based on OECD research and discussions on perception surveys that were conducted in a two-day workshop in Istanbul, Turkey. The workshop was hosted by the Office of the Prime Minister of the Turkish Government, on 21-22 June 2010. Forty delegates to the Regulatory Policy Committee and experts from 15 countries met to share experiences on the topic of "Measuring progress in regulatory reform through the use of perception surveys." The meeting was chaired by Mr. Jeroen Nijland, Director, Regulatory Reform Group, Ministry of Economic Affairs, Agriculture and Innovation, the Netherlands. Discussions were conducted under Chatham House Rules. Citations are therefore limited to published material. Publicly available background reports and presentations at the workshop are available on the website: *www.oecd.org/regreform/perceptions*. This guide also draws on factual information relating to perception surveys in OECD countries that was provided by delegates to the OECD Regulatory Policy Committee in 2010. Overview tables on the use of regulatory perception surveys in OECD countries are available in the Annex.

The workshop and subsequent research are part of the programme on Measuring Regulatory Performance. It aims to assist OECD countries in the design and use of indicators for communicating progress, for diagnosing successes and failures, and for improving regulatory policies, programmes and tools. Further information on the programme can be obtained from *www.oecd.org/regreform/measuringperformance*.

The OECD Regulatory Policy Committee

The mandate of the Regulatory Policy Committee is to assist members and non-members in building and strengthening capacity for regulatory quality and regulatory reform. The Regulatory Policy Committee is supported by staff within the Regulatory Policy Division of the Public Governance and Territorial Development Directorate. For more information please visit *www.oecd.org/regreform.*

The OECD Public Governance and Territorial Development Directorate's unique emphasis on institutional design and policy implementation supports mutual learning and diffusion of best practice in different societal and market conditions. The goal is to help countries build better government systems and implement policies at both national and regional level that lead to sustainable economic and social development.

We would welcome your feedback on this guide. Please visit *www.oecd.org/regreform/measuringperformance* to fill out a short online questionnaire.

Policy Conclusions

Perception surveys are an increasingly integral component of a business- and citizen-centred approach to regulatory reform, as a means to assist governments with better results in an open, democratic system. This guide helps officials planning perception surveys or engaging external expertise to use perception surveys for evaluating and communicating progress in regulatory reform. It explains the challenges involved in the design and use of business and citizen perception surveys – and ways to overcome them. It will also help officials responsible for writing and evaluating tenders for surveys judge the quality of consultants' work and get the most out of survey results. The guide is written in non-technical language for a broad audience, drawing on examples from the regulatory field.

The following ten key policy messages are presented in this guide:

1. **Understanding and improving the perception of the regulatory environment matters to performance.** Positive perceptions of regulations can influence investment decisions and promote respect for and compliance with regulations. (Introduction)

2. **Perception surveys are increasingly used in OECD countries** to evaluate the performance of regulatory reform programmes, in particular in the area of reducing administrative burdens. Perception surveys are further used to obtain information on the level of awareness and confidence in regulatory reform programmes among businesses and citizens, and as a diagnostic tool to identify areas of concern to business and citizens in order to inform future regulatory reforms. (Chapter 1)

3. **If pitfalls in survey design are ignored, survey results become unusable for policy makers.** There are a surprising number of pitfalls in designing surveys. For example, even the order and phrasing of questions can affect responses and the quality of survey results. (Chapter 2)

4. **Using good practice methodologies will improve the quality of results considerably** and help to avoid pitfalls. For example, it is advisable to run pilot surveys to identify questions that respondents have difficulty understanding and then adjust questions accordingly. (Chapter 3)

5. **Perceptions and hence survey results are shaped by many factors; the actual quality of regulations is only one of them**. For example, perceptions of the quality of regulations can be influenced by trust in government, the current economic situation, experience with front-line service, prior expectations and the content of government (and general media) communication. (Chapter 4)

6. **It is necessary to look beneath survey results.** The same survey results may be driven by very different underlying factors. In-depth questions and selected qualitative research techniques can prove very valuable in bringing to light the reasons for the results and drawing concrete policy conclusions from survey results. (Chapter 4 and 5)

7. **Irritation from experiences with regulation and frontline service can account for a significant degree of business and citizens' dissatisfaction with regulation**. This experience is often more negative than might be suggested by the measurable costs of administrative burdens. (Chapter 4 and 5)

8. **Perception surveys also have their limitations**. Experience suggests the likelihood of a disparity between the perceived quality of regulations as reported by business and citizens and the measurable results of regulations. For example, in many countries surveys have tended to reveal negative perceptions of the quality of regulations while more fact-based measurements have shown an improvement. This appears to apply particularly to programmes targeted at reducing administrative burdens. (Chapter 5)

9. **A comprehensive evaluation system should include different types of indicators**, each revealing different information for policy evaluation. Discrepancies in results can highlight the need for deeper analysis to evaluate and inform policies. (Chapter 5)

10. **Perception surveys are an integral part of a two-way communication strategy with stakeholders.** They can serve as a means to communicate stakeholder views to the government, and discussion of the results can lead to fruitful exchanges between government and stakeholders in the case of regulatory reform. Survey results can also help to evaluate the success of the government's communication strategy by assessing stakeholders' level of awareness of recent initiatives. (Chapter 5)

"Men are disturbed not by things,
but by the view which they take of them."
– Epictetus, *Enchiridion*, 5

Introduction

Evaluation and communication in the regulatory reform cycle

As OECD countries continuously strive to improve the quality of their regulations, significant resources have been invested in regulatory policies and reform. In line with the rise in resources allocated, there is increasing pressure for greater accountability and the use of performance information to demonstrate the effectiveness of regulatory programmes.

OECD principles promote the evaluation of the effectiveness of regulatory reform programmes. Figure 0.1 represents the idealised regulatory reform policy cycle showing the links between programme design, programme implementation, communication and evaluation. In this diagram, the aims of reforms are communicated to stakeholders. The quality and results of regulatory programmes are then evaluated and the results of the evaluation should feed back into the subsequent design and implementation of regulatory programmes and communication strategies.

Figure 0.1. Regulatory reform policy cycle
The role of perception surveys in evaluation and communication

Governments want to know how those most affected by regulations – businesses and citizens – perceive the regulatory environment and whether they see the benefits of regulatory reforms. Positive perceptions and stakeholder support are crucial for the success of regulatory reform initiatives, in great part because perceptions of the quality of regulation can influence the investment decisions of firms, and their compliance with regulatory requirements. For example, a household survey of entrepreneurship in the United Kingdom found that individuals' perceptions of business regulations influenced business start-up decisions (Kitching, 2006). Moreover, the Bloomberg-Schumer Report of 2007, which compared perceptions of regulation in the United States and the United Kingdom, reported that financial firms made investment decisions between the United States and the United Kingdom based, in part, on perceptions of three factors associated with regulatory quality: regulatory structure, regulatory approach, and regulatory enforcement (McKinsey & Company, 2007).

Perception surveys can serve three major purposes:

- to evaluate the success of a regulatory reform programme from a user's perspective;

- as a diagnostic and communication tool to identify areas of concern to citizens and businesses, and thus inform future regulatory reforms; and

- to obtain information on citizens' and businesses' level of awareness, confidence, interest, and recognition of regulatory obligations, regulatory reform programmes and regulatory bodies. In some countries, this information serves to evaluate and inform communication strategies.

Structure of the guide

Countries face a number of important interrelated challenges in the design, interpretation and use of perception survey findings. This guide's five chapters explain these challenges and ways to address them. All chapters are written for a broad audience in non-technical language, drawing on examples from the regulatory field.

Chapter 1 provides an overview on the ways OECD countries use regulatory perception surveys. Chapter 2 discusses the pitfalls in designing surveys and Chapter 3 provides step-by-step guidance for designing sound methodological surveys. Chapter 4 analyses the drivers of perceptions that may explain the "perception gap" that arises between the perceived and actual quality of regulations. It also provides guidance on tools to bridge the gap. The last chapter discusses the strategies used by OECD countries to get the most benefit from stakeholder surveys for evaluative and diagnostic purposes and for the communication of reform.

Chapter 1
How OECD Countries Use Perception Surveys in the Regulatory Policy Cycle

Perception surveys are a powerful tool that can be used for a variety of purposes. This chapter provides an overview of the ways OECD countries use perception surveys in the regulatory policy cycle. This chapter also presents how perception surveys used by OECD countries differ in terms of survey design and how they are conducted.

OECD countries commonly use perception surveys to measure the performance of regulatory reform programmes, in particular in the area of administrative burden reduction. Two main categories of surveys can be identified:[1]

- *Surveys on regulatory reform programmes:* Such surveys focus on the evaluation of particular regulatory reform programmes. For example, the Regulation Barometer in Sweden, conducted by the Board of Swedish Industry and Commerce for Better Regulation, evaluates the government's administrative burden reduction programme (see Box 1.1). Another example is the Belgian tax-on-web survey which looks at how satisfied users are with the possibility to complete their tax declarations online as part of the simplification programme.

Box 1.1. The Regulation Barometer: Evaluating the Better Regulation Programme in Sweden

The "Regulation Barometer", conducted by the Board of Swedish Industry and Commerce for Better Regulation in May 2009, asked 600 proportionately selected entrepreneurs and business leaders over the telephone to comment on the government's Better Regulation Programme, to specify the impact of regulation on their company and to indicate their expectations for the near future.

In order to improve the accuracy and homogeneity of the responses, a definition of relevant terms preceded the actual questions, where appropriate. For example, one question asked: "By regulations we intend all laws and rules that you as an entrepreneur and your company have to comply with. Do you think it is important for the Government to simplify regulations that affect business?"

The results of the survey indicated that most of the businesses were aware of the government's reform, indicating that the communication strategy was successful. However, 75% of respondents thought that the burden of regulation had remained almost the same over the last 12 months and still 58% said that administrative burdens would be more or less the same in the following year – despite the government's plans.

According to the Board of Swedish Industry and Commerce, the survey fulfilled two purposes. It was designed to present businesses' perception of regulation and also to put pressure on the government to start evaluating the results of its Better Regulation Programme.

Box 1.2. The benefits of regulation: Perception of smoke-free environments

The UK Better Regulation Executive commissioned a survey which looked at citizens' perception of regulation in general and in specific areas of direct concern to citizens: Health and safety at work, Environmental standards, Food hygiene regulations and Smoke free environments.

The study, conducted by FreshMinds, consisted of more than 1 000 personal interviews with private individuals carried out proportionately across the country. For each of the specific areas, respondents were asked to answer to five statements, using a 5-point scale from "strongly agree" to "strongly disagree".

In the case of Smoke free environments (see figure below), "broad support for regulation tended to exist". Interestingly, support for smoking regulation differed considerably across regions (65% in the North-West compared to 89% in the North-East), age groups (individuals aged 55+ more in favour than younger age groups) and social grades (affluent members of society more in favour than semi or unskilled workers or people on benefits).

The survey's results will "inform future work, in areas such as Impact Assessments".

Response to all tested statements on smoke-free environments
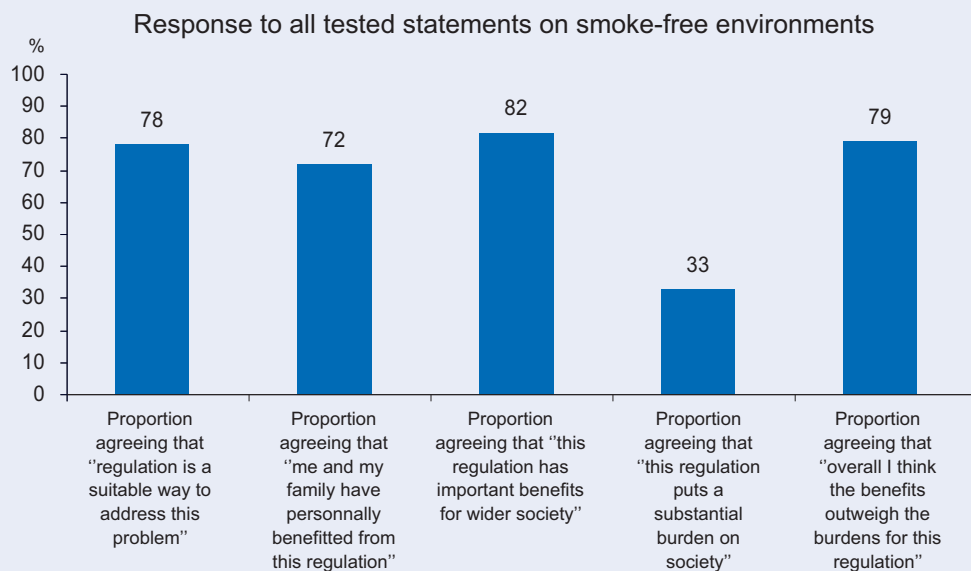

Source: See both the main report and the research report at *www.bis.gov.uk/policies/better-regulation/benefits/better-benefits;* see also Overview Table A.1 in the Annex and Table A.2 at *www.oecd.org/regreform/measuringperformance.*

- *Surveys on individual regulations and agencies:* In contrast to surveys on regulatory reform programmes, little information has been found on surveys which look at the performance of individual regulations and agencies. For example, the UK survey "The Benefits of Regulation: A public and business perception survey" included questions about individual regulations such as the smoking ban, maternity and paternity leave regulation, food hygiene, alcohol licensing and discrimination regulation (see Box 1.2 above). The results of the survey will inform the assessment of future regulatory initiatives.

Characteristics of questionnaires

Within these two categories – surveys on regulatory reform programmes and surveys on individual regulations and agencies – questionnaires are designed to fulfill one or more of the following three functions:

- *Evaluation:* Questions can be designed to evaluate specific regulations, or the success of regulatory reform programmes. For example, the Regulation Barometer conducted in Sweden asked whether respondents thought that it had become easier or more burdensome for them and their company to comply with government regulation over the previous 12 months;

- *Information on awareness level:* Some surveys contain questions about business and citizens' level of awareness of regulations, regulatory reform programmes and regulatory bodies. For example, the Canadian Survey of Regulatory Compliance Cost asked small and medium-sized businesses: "Are you aware that over the last three years, the federal, provincial, and municipal governments have been implementing initiatives to reduce the cost of regulatory compliance for small businesses?";

- *Diagnosis to inform future reform:* Perceptions surveys can also be designed for use as a diagnostic tool in order to identify areas of concern to the general public or to stakeholders, thus facilitating future regulatory reforms. The Irish Business Regulation Survey, for instance, included the following

question: "Which area of regulation do you think that the Government should tackle as a priority? Please think specifically of the regulations affecting each of these areas rather than other issues such as investment in the areas."

In addition to those categories and functions, surveys differ with respect to a number of other characteristics.

- *Target population:*

  - Most surveys, for which the OECD has information, targeted businesses. Surveys differed with regard to the size of businesses sampled. The Finnish SME Barometer, for example, focused exclusively on small-medium enterprises while the Dutch Macro Business Sentiment Monitor sampled businesses of varying size, sector, and life cycle.

  - Some surveys were directed towards the general public regardless of the respondents' involvement or knowledge of the subject in question. Others targeted explicitly citizens or businesses directly concerned by specific regulations or administrative burdens, or users of particular services. For example, the Belgian 'Tax-on-web satisfaction survey' and the Turkish 'Customer Satisfaction Survey' aimed to measure the performance of on-line services which were designed to simplify administrative procedures, and therefore only addressed users having already had experience with those services.

- *Number of respondents:* The number of respondents in the surveys ranged from 15 to more than 10 000. For example, surveys of business leaders usually had a small sample size: The survey "Regulation Barometer", a survey of entrepreneurs and business leaders in Sweden, sampled 600 respondents. In contrast, the Canadian Federation of Independent Business (CFIB) Survey interviewed 10 566 small- and medium-sized business owners.

- *Repetition of surveys:* Some surveys were conducted only once, while others are repeated, most of them annually or biannually. The Survey on Administrative Burdens in Belgium, for example, has been conducted on a biennial basis since 2000.

- *Type of questions:* Some questions are very specific, while others are more general. The Belgian Citizen Satisfaction Survey, for example, asked very specifically: "How do food chain operators feel about controls and the services provided by the Federal Agency for Food Chain Security?" An example for a more general question can be found in the Korean Regulatory Reform Satisfaction Survey which asked respondents: "How satisfied are you with the regulatory reform process in general?" Furthermore, some questions ask about respondents' direct experience with regulations or regulatory reform as opposed to their general opinion. For example, the Dutch Perception Monitor Regulatory Burden asked: "If you look at the regulatory burden of the government that affects your business, has this increased, decreased, or remained more or less equal compared to the situation one year ago?"

- *Answer choices:* Another aspect of question design concerns the answer choices given to respondents. Many surveys (e.g. surveys conducted in Australia, Korea, the Netherlands, New Zealand, the United Kingdom) employed questions using a scale to measure perceptions of compliance burden. For example, the Dutch Perception Monitor Regulatory Burden inquired: "Can you indicate by giving a mark ranging from 1 to 7 to what extent the regulatory burden impacts your business operations? Figure 1 means 'not at all' and 7 'severely'." Other questions, especially those dealing with awareness, used a simple yes-or-no format.

- *Data collection method:* Common methods to collect data are phone or personal interviews, and paper or online questionnaires. For example, interviews for the Australian Business Perception Survey were conducted via telephone, partly with computer assistance. 'The Benefits of Regulation: A public and business perceptions study', conducted in the United Kingdom, consisted of more than 1 000 personal interviews. In some cases, different data collection methods were combined: The Irish "Better Regulation Survey" combined its postal survey with intensive telephone follow-up. In addition, 32 of the more than 800 respondents to the postal survey were selected for an additional qualitative interview via telephone.

- *Source:* Many surveys were initiated by government ministries (the Norwegian Ministry of Trade and Industry, for example), others by business organisations (Board of Swedish Industry and Commerce for Better Regulation, among others). Consultancy firms and research institutes were frequently entrusted with conducting the surveys. For example, the survey "Perception Monitor Regulatory Burden" was commissioned by the Dutch Regulatory Reform Group (Ministries of Finance and Economic Affairs) and was conducted by the market research company Stratus. Finally, some private research companies such as Gallup routinely provide data on perceptions of regulations.

Table A.2 (available online at *www.oecd.org/regreform/ measuringperformance*) provides information on the key findings of surveys. While it is difficult to compare the findings of surveys that differ significantly with respect to their focus and design, some patterns in the results can be identified:

- The results of a number of surveys indicate that businesses are often aware of government programs and intentions to reduce administrative burdens (e.g., in the Netherlands, New Zealand, Sweden and the United Kingdom), but many doubt that governments can or are successfully realising their targets;

- Despite large investments in regulatory reform programmes, among the surveys for which the OECD has information, few indicate that stakeholders perceive improvement.[2] More frequently, no improvement is reported. The Canadian, Swedish and British surveys, for example, inquired whether or not administrative burdens and/or compliance costs have decreased over the recent past. Stakeholders indicate no or, at best, very limited improvements – despite the considerable emphasis placed on administrative simplification in these countries and more fact based analysis supporting reduction in administrative burdens.

Do these findings mean that the regulatory reform programmes were a failure? Not necessarily. Negative survey responses can also stem from the design of the survey (see Chapters 2 and 3), the current economic situation, government and media communication, experience with front-line service and prior expectations (see Chapter 4) The explanation for the negative findings is likely to be different for different countries and

surveys. Understanding and interpreting the reasons underlying these responses is therefore very important to identify the best policy responses (see Chapter 5).

Conclusion

Perception surveys are increasingly used in OECD countries to evaluate the performance of regulatory reform programmes, in particular in the area of reducing administrative burdens. Perception surveys are also used to obtain information on citizen and business levels of awareness and confidence in regulatory reform programmes, and as a diagnostic tool to identify areas of concern to business and citizens as a means to inform future regulatory reforms. Results of a number of surveys in OECD countries indicate that most often it seems that businesses do not feel any improvement in the regulatory environment. These findings do not necessarily indicate a failure of regulatory programs, as survey responses are influenced by many other factors. The aim of this guide is to assist officials to understand the reasons for positive or negative survey results and maximise the benefits from stakeholder surveys for evaluating, communicating and improving regulatory policy.

Notes

1. This chapter draws on information provided by OECD member officials in 2010 on perception surveys in their countries. Please see Tables A.1 and A.2. Table A.1 in the Annex summarises information on the focus, purpose, target population and methodology used for each survey. Table A.2 (available online at *www.oecd.org/regreform/measuringperformance*) provides more detailed information including survey questions, key findings and some information on the policy use of the results.

2. One of the few surveys that report an improvement is the "Administrative Burdens in Belgium" survey. Results indicate that businesses estimate the costs of administrative burdens to be lower in 2008 than in 2000 (see Tables A.1 and A.2).

Chapter 2
Understanding Pitfalls in the Design of Surveys

There are a surprising number of potential pitfalls in survey design and, if ignored, survey results can become unusable for policy makers. This chapter provides an analysis of the most common pitfalls, as well as signposts to where information can be found to address them, both within this guide and from external sources.

There are a surprising number of potential pitfalls in survey design and, if ignored, survey results can become unusable for policy makers. Officials who design surveys, write tender proposals to commission surveys, judge the quality of consultant's work or are consumers of survey results are therefore well advised to be aware of the pitfalls.

Pitfalls in survey design

Survey design and methodological choices are often made unconsciously, without awareness of their impact on survey results. The following list points out the most common pitfalls and directs the reader to potential solutions:

- *Questions suggesting answers:* The phrasing of questions and the distribution of answer choices may suggest answers to respondents. For instance, survey respondents are more likely to agree to the question "Should the government increase social spending for *people with low* income?" than to the question "Should the government increase social spending for *people on* welfare?" (Rasinski, 1989).

  Suggestion: follow Steps 2 and 3 in Chapter 3; see also Fowler 1995, pp. 73-75, and Iarossi 2006, pp. 32-37.

- *Question priming:* Previous questions may suggest answers; respondents answer questions differently based on the information provided by previous questions. The effects of "question priming" are detailed in Box 2.1. Many perception surveys focus on costs and burdens associated with regulations. If businesses first need to respond to a number of questions related to costs and burdens, they may be more inclined to answer negatively to questions about regulatory quality in general than if they were asked questions about the positive effects of regulations beforehand.

  Suggestion: follow Steps 2 and 3 in Chapter 3; see also Iarossi 2006, pp. 74-78, and Van de Walle / Van Ryzin, 2011.

Box 2.1. Question priming and citizen satisfaction

Changing the order of the same questions in a survey can have a significant impact on the survey results and interpretations. In the citizen satisfaction survey modelled below, questioners switched the question order of specific public services versus general satisfaction with public services. The results of Version A and B were significantly different, even though the services clearly did not change.

Under Version B, overall satisfaction was significantly lower when people thought about their satisfaction after rating individual public services. Version A yielded higher overall satisfaction when asked about satisfaction before rating individual services.

Version A	Version B
Rating of a city and its political leaders (4 questions)	Rating of a city and its political leaders (4 questions)
↓	↓
General satisfaction with public services (3 questions)	Rating of specific public services (11 questions)
↓	↓
Rating of specific public services (11 questions)	General satisfaction with public services (3 questions)
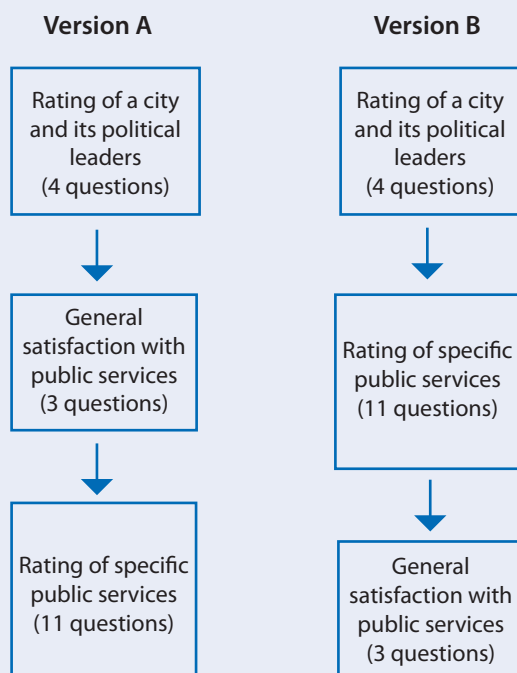

This example was taken from Van de Walle, Steven and Gregg G. Van Ryzin (2011), "The order of questions in a survey on citizen satisfaction with public services: lessons from a split-ballot experiment", in *Public Administration*.

- *Complexity:* Respondents easily get confused by technical jargon and complex answer options. Using many words to define a single concept within one question can also be difficult to understand. For example, the following question introduced in the UK Better Regulation Survey did *not* work, because the question introduced the parallel concepts of 'regulation' and 'protection' in the same question, confusing respondents (Russo, 2010):

  – How far do you agree with each of the following two statements?

    – There is too much *regulation*.

    – There is not enough *protection.*

  Suggestion: follow Steps 2 and 3 in Chapter 3; see also Fowler 2009, pp. 93-95; p. 110, and Iarossi 2006, pp. 37-43.

- *Scale type:* Choice of scale influences survey results. For example, the results in one survey question using a scale from 1-7 were reported to be significantly different from the results using a scale from 1-5. This can happen because respondents may show arbitrary tendencies to answer at the median (3) more often in a 1-5 scale than in a 1-7 scale (Kwon and Kim, 2010). Furthermore, answers to the same scale may differ across country/cultural context. For example, on a scale from 0 to 10, a score of 5 does not necessarily mean a "pass" in all countries. In the Netherlands, students pass with a 5.5, in Brazil with a 6 and in Albania with a 4. In some other countries 0-10 scales are not commonly used. For instance, 2-6 is the standard scale in Bulgaria and -3-12 is the standard scale in Denmark (Van de Walle, 2010).

  Suggestion: follow Steps 2 and 3 in Chapter 3; see also Fowler 2009, pp. 101-103; pp. 110-111, and Iarossi 2006, pp. 59-65.

- *Questions mean different things in different countries:* Simple concepts have different meanings in different countries, and ideas can be lost in translation. Even if two countries share the same language, concepts may differ (see Box 2.2).

  Suggestion: follow Steps 2 and 3 in Chapter 3; see also Iarossi 2006, pp. 85-86, and Harkness *et al.*, 2010.

Box 2.2. Conceptual differences across nations

When asking questions about confidence in the civil service, the World Value Survey incorporated different translations to represent the same concept in different nations (here, the concept was "the civil service"). The translation in Mexico, *la burocracia pública*, has much stronger negative connotations than the Argentinean translation, *los funcionarios*. This difference in phrasing may create a negativity bias with respect to the results in Mexico when compared with those in Argentina.

Example: World Value Survey 'Confidence in the civil service'

Argentina (Los Funcionarios)

Chile (La Administración Pública)

Mexico (La Burocracia Pública)

Venezuela (La Administración Pública)

Peru (Los Funcionarios Públicos)

Puerto Rico (Los Funcionarios De Gobierno)

Spain (La Administración Pública: Los Funcionarios)

Venezuela (La Administración Pública)

Source: Van de Walle, Steven (2010), "Measuring citizens' perception of the public sector", presented at the OECD Workshop on Measuring Progress in Regulatory Reform: Perception Surveys, 21-22 June, Slide 14.

- *Definitions:* The way regulation is defined in a survey, if at all, has several implications for survey results and interpretation:

  - First, the word "regulation" has multiple meanings for many respondents. If regulation is only defined broadly (or not at all), survey results are difficult to analyse and compare. The reason is that survey participants may be responding with different ideas of "regulation" in mind or may not understand at all what regulation means. The UK Better Regulation

Study documented that participants' ideas of regulations differed between primary laws, agency rulemaking, self-regulation by businesses or obligations on citizens like speed limits.

– Second, when regulation is not defined, answers to general questions about regulation may be formed more by the negative connotations of the word 'regulation' than by perceptions of actual regulation (negativity bias). The reason is that the word 'regulation' has an inherent negative association in several cultural contexts. For example, Goddard (2003) identifies a strong negative connotation of the word 'regulation' in the US across sectors. And Cosh and Wood (1998) find that although businesses in the United Kingdom did not have serious concerns with the measures that make up regulation – legislation, legal rulemaking, norms, and taxation – they had significant concerns about the word "regulation" in general.

Suggestion: follow Steps 2 and 3 in Chapter 3; see also Fowler 1995, pp. 13-20, and Iarossi 2006, pp. 37-38.

- *Focus of survey and balance of questions:* Most perception surveys focus on costs and burdens, and few ask about the benefits of regulations. This may bias results towards negative perceptions.

  Suggestion: follow Steps 2 and 3 in Chapter 3; see also *questions suggesting answers* and *question priming.*

- *Strategic responses and social desirability:* People often lie in surveys, either in order to promote their interests or to look socially desirable. For example, businesses may report higher regulatory burdens than they actually perceive, in order to motivate additional action by governments. Survey respondents may also answer based on what they think is socially desirable, especially in face-to-face situations.

  Suggestion: follow Steps 2, 3 and 4 in Chapter 3; see also Fowler 2009, pp. 108-110, Marsden/Wright 2010, pp. 285-287, and Fowler 1995, pp. 28-45.

- *Uninformed respondents:* Policy makers can choose to survey business and citizens in general, or target those with direct experience with particular regulations and agencies. Studies find that responses vary according to the level of knowledge and personal experience with regulations. A study conducted in the United Kingdom for instance identified that people having significant experience with regulations exhibited a more balanced view of regulation, acknowledging costs and benefits. Meanwhile those with less experience had less understanding and more polarised opinions. This might be explained by the fact that low awareness of regulation is linked to "an emotional rather than rational response to regulation" (FreshMinds, 2009, p. 27). The study further finds that "more informed citizens are usually more positive about regulation, though this seems less strongly the case for business" (UK Department for Business Innovation and Skills, 2009, p. 69).

  Suggestion: follow Steps 1, 2 and 3 in chapter 3; see Fowler 2009, pp. 106-108, and Iarossi 2006, pp. 27-28.

- *Non-respondents:* Many people who receive a survey do not answer it. If those who ignored the survey would have answered differently than respondents, survey results are biased. For example, many questionnaires ask businesses whether they feel an improvement with respect to regulatory burdens. If businesses that feel the improvement do not bother to answer, and only those who still feel high burdens answer, the results will be more negative than the views of all businesses. Or, if burdens differ for big companies and for small companies, and only big companies fill in the survey, the answers will not be representative of all businesses.

  Suggestion: follow Steps 4, 5 and 6; see Fowler 2009, Chapter 4, and Lohr 2010, Chapter 8; pp. 533-535.

Conclusion

Common pitfalls in survey design include overly complex questions, missing definitions and question priming, i.e. respondents are inclined to answer based on the information provided by previous questions. Furthermore, many perception surveys focus on costs and burdens, and few ask about benefits of regulations. This may bias results towards negative perceptions. If these pitfalls are ignored, the results become unusable for policy makers. It is therefore important to keep pitfalls in mind when designing surveys or judging the quality of consultant's work. The next chapter will offer step-by-step guidance to design methodologically sound surveys that avoid pitfalls or mitigate their effects.

Chapter 3
Good Practices in Survey Design Step-by-Step

Good practice methodologies considerably improve the quality of results and help avoid pitfalls. This chapter explains good practice through sequential, step-by-step guidance that can be used to design a perception survey. It provides advice on how to define survey objectives and the target group, draft survey questions, pilot and re-adjust a questionnaire, select respondents and data collection methods, run the survey, and analyse the results.

Good practice methodologies considerably improve the quality of results and help avoid pitfalls. This chapter explains good practice through sequential, step-by-step guidance that can be used to design a perception survey. The sequential order is important: a step skipped at the outset cannot be returned to later in the process. For example, if survey questions are not carefully designed, even the best methods to collect, analyse and display the data at later stages cannot make up for the bad design. The consequence is that the results can be useless for policy makers.

Six steps to better survey design

Step 1. Define survey objectives, use of results and target population

First, when developing a survey it is important that objectives be clearly defined, *i.e.* what insights should be gained from the survey and what should be learned. Policy makers also need to decide whether they want to compare survey results over time. In this case, the survey should be repeated over time and the questions have to be very carefully drafted to allow for comparisons over time. Furthermore, as changing the questions at the next round compromises the comparability over time, it is advisable to invest in extremely good question design and testing for the baseline survey.

Second, it is timely to consider the question as to whether a perception survey is the right tool to use to achieve the objective and what its limitations are in achieving the objective. For example, to evaluate the success of administrative burden reduction programmes, it is misleading to rely solely on perception surveys, as perceptions and hence survey results are shaped by many factors and the actual quality of regulations is only one of them (see next chapter).

It is therefore advisable to collect other available data that will contribute to achieving the objective and will complement the information obtained from the perception surveys. For example, data based on the Standard Cost Model and on perception surveys provide information on reductions in administrative burdens from different angles.

Checklist to commission, design and run a perception survey

Step 1. Define survey objectives and target group

- Define the objectives
- Define the final use of the results
- Ensure a perception survey is the adequate tool
- Define target group(s)

Step 2. Draft survey questions

- Set up discussions with members of a target group to identify key issues
- Translate those into questions and answer categories
- Draft simple and clear questions
- Keep the questionnaire short to maximise response rate and concentration
- Ensure respondents have the opportunity to report problems

Step 3. Pilot and re-adjusting the questionnaire

- Test the survey on a smaller-scale target group to identify weaknesses in the survey design
- Possibly ask volunteers to think aloud while answering questions and analyse what motivated their answers
- Adjust questionnaire if needed

Step 4. Select respondents and the data collection method

- Select a sample either by random sampling or other methods
- Ensure that the sample size allows to draw valid conclusions from the results
- Choose the data collection method: personal interviews, telephone interviews, Internet surveys, email surveys, etc.
- Maximise response rate through appropriate data collection method

Step 5. Run the survey

- Ensure high response-rate through follow-up emails otherwise conclusions to the survey could be biased
- Use trained interviewers to avoid unintentional influence on responses

Step 6. Analyse the results

- Interpret results as perceptions rather than facts
- Take into account the response rate. A low rate means that no general conclusions can be drawn
- Take into consideration the number and the way respondents have been selected in the result analysis
- Understand how results were reached is essential to draw policy conclusions
- Attach documentation regarding Steps 1-6 to results and interpret results in combination with other data sources

Third, this is the right moment to think about how the final results will be used. The reason for doing this early in the process is that the desired use of the results determines the questions and the target population. For example, the objective of one survey might be to measure the level of awareness of businesses of recent regulatory reforms. If the results of the survey should then be used to adjust the communication strategy, questions that help understand how respondents inform themselves about reforms and how to best reach them could be added.

Fourth, the target population to be surveyed (also referred to as the target group) needs to be identified, including sub-groups. For example, if the target population is businesses, a comparison of the answers of SMEs to those of larger companies could be useful. This decision will have implications for steps later in the process, such as deciding on the number of respondents and the way they are selected. At this stage, deciding to target only those with direct experience with the survey topic could be a possibility, for example those directly affected by administrative burden reduction programmes or those with regular contact with a regulatory agency. Targeting groups with direct contact may lead to more meaningful and informed responses. At the same time, such targeted surveys are not informative about the perceptions and the awareness level of citizens and businesses in general. It is also possible to measure and to distinguish between uninformed and informed respondents. For example, the practice of introducing screening questions to determine if the respondent is qualified to answer questions of interest is used in Canada (Turcotte, 2010).

Step 2. Draft survey questions

Much of what can go wrong in survey design happens at the drafting stage of the questionnaire (see previous section on pitfalls). A number of good practices can help produce a sound questionnaire.

Respondents can get easily frustrated when a survey does not include any questions on the most bothersome problems. This can occur because the person who designed the survey was not aware of these problems or did not realise their importance to respondents. Thus, before beginning the process of drafting questions, it is advisable to conduct focused discussions with individuals of the target population about the issues to be tackled. For example, if the objective of the survey is to identify what irritates business the most when dealing with regulation, a focus group

with business representatives can help identify key issues that can then be transformed into questions, and answer choices. This ensures that survey respondents identify with the questions and answer choices.

Box 3.1. Checklist for drafting good questions

1. Do the answers to the questions help meet the objectives of the survey?

2. Do the questions address the most bothering issues of the target population?

3. Is the language simple and devoid of technical jargon?

4. Are key terms such as "regulation" clearly defined?

5. Do you avoid asking two questions in one, i.e. do all questions only ask one question at a time?

6. Are questions clear and precise enough that they will be consistently understood in the same way by all respondents?

7. Are the formulation of questions and answer choices and their order as neutral as possible, i.e. do they avoid suggesting answers?

8. Are the answer choices and scales clearly defined and consistently understood across respondents? Have both been chosen carefully?

9. Does the target population have the capacity and knowledge to answer all questions?

10. Have screening questions been included, that is, has the same question been asked in different ways to identify consistent respondents and meaningful responses?

11. Have tricky questions been included towards the end of the survey when respondents feel more comfortable answering them?

12. Is the questionnaire short enough to ensure that respondents will concentrate until the end?

For a more detailed checklist, see also Fowler, Floyd J., Jr. and Carol Cosenza (2008), "Writing effective survey questions", *in:* De Leeuw, Edith D., Joop J. Hox and Don A. Dillman (eds.), *The international handbook of survey methodology*, Mahwah, NJ: Lawrence Erlbaum, p. 159.

Once key issues have been identified, simple and clear questions can be drafted. Ensuring that respondents have a shared understanding of the meaning of the question and that they know the answer to the question is important. If not, the answers given by respondents are not comparable and policy makers cannot draw any meaningful conclusions from the results. Box 3.1 above highlights key recommendations for drafting good questions in a checklist format. Once drafted, using the online tool "Question Understanding Aid" from the University of Memphis for further checking may be helpful (see *http://mnemosyne.csl.psyc.memphis.edu/QUAID/quaidindex.html).* It analyses questions and points to problems with the questions such as unfamiliar technical terms, vague or imprecise terms or complicated syntax.

At this stage, a letter of invitation to participate in the survey can be drafted. It should indicate the purpose of the survey, clearly define the participants' role and explain how anonymity will be guaranteed. The survey's cover letter is extremely important, as a good letter helps maximise the response rate. Low response rates present the risk that no statistically valid conclusions can be drawn from the survey results.

Step 3. Pilot and re-adjust questionnaire

It is essential to test surveys to identify weaknesses in the survey design. This involves running the survey on a smaller-scale group of people beforehand to learn how respondents are likely to interpret and react to the questionnaire. Piloting surveys allows researchers to discover problems in the survey design such as poorly-phrased questions and to adjust the survey design accordingly. This relatively small investment before running the actual survey can significantly improve the quality of results. In addition, the analysis of responses to the pilot survey enables policy makers to subsequently better interpret answers to the survey questions. It can enable policy makers to identify the key drivers of perceptions, as well as test respondents' associations with and understanding of regulation (Russo, 2010; UK Department for Business Innovation and Skills, 2009).

Pilots usually draw on qualitative research methods such as "cognitive laboratory interviews" where interviewers work with volunteers to find out whether:

- Questions are consistently understood across respondents;

- Answers accurately describe what respondents have to say;

- Answers provide valid measures of what the question is designed to measure;

- Respondents have the information needed to answer the questions (Fowler, 2009).

Typically, volunteers from the target population respond to the questionnaire and are asked by interviewers to "think aloud" while they are preparing their answers. They may also be asked some follow-up questions to understand the way in which they interpreted and answered each question. Standard follow-up questions ask respondents to *i)* say in their own words what they think the question is asking and *ii)* to explain how they chose a particular answer over others. Interviewers need to be knowledgeable about the objectives of each question, so that they can detect issues arising from the way that respondents understand questions (Fowler, 2009). They also need to be trained not to influence respondents in their answers. Detailed information on how to conduct such interviews can be found in DeMaio & Rothgeb, 1996 (see Box 3.2). Following the interview results, phrasing and question order can be adjusted.

Lessons learned in Canada show that pilot surveys should include open-ended questions. This allows policy makers to subsequently build well thought-out and clearly-stated choices to closed-ended quantitative questions (Turcotte, 2010). The UK Better Regulation Executive (BRE) piloted questions with qualitative research methods to "better understand how individuals intuitively think about regulation" (FreshMinds, 2009, p. 108) and to adjust the wording of questions in the quantitative survey. In response to concerns in the pilot survey over question complexity, the final quantitative survey used simple language, avoiding the word "proportionate" in particular. The BRE further used its insights from the qualitative phase to design questions in the quantitative survey so that "they [the respondents] were not forced into answers that limited the range of their responses" (FreshMinds, 2009, p. 114). Whereas open-ended questions are very valuable for pilot surveys, experience from Belgium suggests that using them in the final surveys risks diminishing the response rate.

It can be useful to not only test the questions, but also the cover letter: Is the purpose of the survey clear to respondents and do they feel the letter motivates them to participate?

Step 4. Select respondents and the data collection method

This stage confirms the number of respondents and the way they are selected. If done correctly, general conclusions can be drawn about the views of the target population based on a small number of respondents. For example, when properly selected, a survey of 1 000 citizens can allow a researcher to draw conclusions about the views of all citizens in a country. If, on the contrary, there are mistakes in the selection of respondents, the results of the survey can be biased to the point of being useless.

The method used to select the people who receive the survey (*i.e.* the sample) is called *sampling methodology* in statistics. One common method used is random sampling. Random sampling is a process that randomly selects respondents from the target population. For example, if the target population is "companies in a country", all companies should have the same chance of being selected, and only once. This is easy if all companies in the country are listed. In this case, a random number generator can simply be used to select respondents. Additional sophisticated methods exist that help reduce survey costs or ensure that there is a sufficient sample size for each sub-group of interest (*e.g.* SMEs versus large companies). For example, stratified sampling is a process that generates random samples for a number of sub-groups. For further detailed advice on choosing survey respondents, see for example Lohr, 2010.

Selecting the right sample size is quite complex. Contrary to common belief, it does not depend on the size of the target population. For example, whether a country has 300 000 or 80 million inhabitants, the sample size is constant. The right sample size depends on other factors such as the method used to select respondents, the number of sub-groups compared and measurement and sampling error. Relying on a statistician to choose the right sample size and methodology is advisable (see Box 3.2). Note that tables that indicate the right sample size often assume a 100% response rate. If a response rate is suspected to be lower, the sample size needs to be adjusted upwards.

A high response rate is important for drawing valid result conclusions. This is particularly the case if those who ignored the survey would have answered differently than respondents. For example, in customer satisfaction surveys, those who are unhappy with the service may answer the survey to channel their anger and to ask for change, while those who liked the service may not bother responding. In this case, survey results are biased and the bias will be more important if the

response rate is low. It is often difficult to find out whether non-respondents would have answered differently (see Step 6). Ideally a data collection method therefore maximises the response rate, while ensuring the anonymity of respondents and making them feel comfortable to respond honestly. Table 1 lists advantages and disadvantages of common data collection methods. One can choose between self-administered data collection methods (e.g., Internet surveys) versus interviewer-administered data collections (e.g., personal interviews). Self-administered surveys are usually less expensive than interviewer-administered data collections and respondents are more likely to honestly respond to sensitive questions if no one sees how they answer. However, interviewer-administered data collections are often most effective for getting a high response rate and for exercising quality control with respect to answering all questions, meeting question objectives, or the quality of answers provided (Fowler, 2009). At this stage, it is timely to design ways to follow-up with non-respondents to maximise response rates.

Table 3.1. Advantages and disadvantages of data collection methods

Data collection method	Advantages	Disadvantages
Interviewer-administered		
Personal interviewing	• Effective way of getting people to participate • Rapport and confidence building possible • More time-consuming surveys are possible than by any other method • Best for some sample designs (e.g. area probability samples)	• Likely to be costly (trained interviewers needed on site) • Data collection period likely to be longer than telephone procedures • It might be difficult to reach every person in your sample
Telephone interviewing	• Costs are usually lower than for personal interviews • Response rate is likely to be higher than from a mail sample • Provides better access to certain populations, especially compared to personal interviews • Data collection periods are usually short	• Possibly sampling limitations (omits those without a landline or whose phone number cannot be found) • Possibly less appropriate for personal or sensitive questions

Table 3.1. Advantages and disadvantages of data collection methods (*cont.*)

Data collection method	Advantages	Disadvantages
Self-administered		
Group administration	• Costs are generally low • Participation rates are generally high • Possible to explain the study and answer questions upfront	• It is often not feasible to bring all people selected for the survey together into one physical location
Mail procedures	• Costs are relatively low • Minimal staff and facilities required • Provides access to widely dispersed samples and for samples that are difficult to reach via other means • Respondents have time to give thoughtful answers	• May not be an effective way of getting people to reply (depending on sample and topic) • Good mailing addresses for people selected for your survey needed
Dropping off questionnaires at households	• Interviewer can explain the study, designate a household respondent and answer questions • Trained interviewing staff not required • Respondents have time to give thoughtful answers	• Costs about as much as personal interviews • Field staff is required
Internet surveys	• Costs are low • Potential for high speed returns • Respondents have time to give thoughtful answers	• Challenge of getting people to reply (depending on people surveyed and topic) • Respondents are limited to Internet users • Correct set of email addresses is needed

Source: Based on Fowler (2009).

Step 5. Running the survey

Running the actual survey is only one of the many steps in the process. Surveys that evaluate or measure awareness of regulatory reform should be timed to take into account the lag between reform implementation and diffusion. To maximise response rates in e-mail surveys, at least three follow-up emails to non-respondents are appropriate, and sometimes more. Non-respondents should understand the importance of their answer. In interview-administered surveys, interviewers should be trained so that they do not unintentionally influence respondents in their answers.

Step 6. Analysing the results

In this step, all survey responses are summarised and analysed. The results can be presented in graphs and tables and explain what conclusions can be drawn from the data. It is advisable to:

- Interpret survey data not as facts, but as perceptions.

- Interpret results together with other data sources.

- Understand what is behind the results to draw policy conclusions (The next chapter explains the fundamental drivers of perceptions and ways to bring them to light.).

- Take into account the number and the way respondents were selected in the interpretation of the results. For example, if random samples were drawn from more than one group, general conclusions about the full group may require some adjustments (Lohr, 2010).

- Take into account the response rate in the interpretation of the results. If the response rate is too low, no generalisations about the views of the targeted population group can be drawn. Groves *et al.* (2001) and Lohr (2010), for example, explain how to deal with non-respondents (see Box 3.2). This may include analysing whether non-respondents would have replied differently than respondents, which would introduce bias into the survey results.

- Document Steps 1 to 6 well and report transparently how the survey was conducted to assist users to interpret the results.

Box 3.2. Literature hints for designing an effective survey

General (all steps)

For general guidance on survey design written in a non-technical way: Fowler, Floyd J., Jr. (2009), *Survey Research Methods*, 4th Edition, Thousand Oaks, CA: Sage.

For more technical guidance: De Leeuw, Edith D., Joop J. Hox and Don A. Dillman (eds.) (2008), *The international handbook of survey methodology*, Mahwah, NJ: Lawrence Erlbaum.

Designing and testing questions

Fowler, Floyd J., Jr. (1995), *Improving Survey Questions: Design and Evaluation,* Thousand Oaks, CA: Sage.

Fowler, Floyd J., Jr. and Carol Cosenza (2008). "Writing effective survey questions", in: De Leeuw, Edith D., Joop J. Hox and Don A. Dillman (eds.), *The international handbook of survey methodology*, Mahwah, NJ: Lawrence Erlbaum, pp. 136-160.

DeMaio, Theresa J. and Jennifer M. Rothgeb (1995), "Cognitive interviewing techniques-in the lab and in the field", in: Norbert Schwarz and Seymour Sudman (eds.), *Answering questions*, San Francisco: Jossey-Bass, pp.177-196.

For a more comprehensive and technical guide to the psychological roots of survey data, how survey responses are formulated, and how seemingly unimportant features of surveys can affect the answers obtained, see Tourangeau, Roger, Lance J. Rips and Kenneth Rasinski (2000), *The Psychology of Survey Response*, Cambridge University Press, Cambridge.

Selecting your survey respondents and dealing with non-responses

For advice on sampling design (how to choose your respondents) and analysis: Lohr, Sharon (2010), *Sampling: Design and Analysis*, 2nd edition, Boston, MA: Brooks/Cole.

For advice on dealing with low response rates: Groves, Robert M. *et al.* (2001), *Survey Nonresponse* (Wiley Series in Survey Methodology), Chichester, England: John Wiley and Sons, Ltd.

Analysing and presenting data

For a basic step-by-step guide on presenting data effectively: Wallgren, Anders *et al.* (1996), *Graphing Statistics & Data*, Thousand Oaks, CA: Sage.

For a more comprehensive guide on analyzing and presenting data: Pearson, Robert W. (2010), *Statistical Persuasion: How to Collect, Analyze, and Present Data…Accurately, Honestly, and Persuasively*, Thousand Oaks, CA: Sage.

Conclusion

Use of good practice methodologies will improve the quality of results considerably and help to avoid pitfalls. First, the objectives and the target population are defined. This is followed by drafting the survey questions, running a pilot and re-adjusting the questionnaire, selecting respondents and the data collection method, running the survey, and analysing the results. The sequential order is important: a step skipped at the outset cannot simply be inserted later. For example, if survey questions are not carefully designed, even the best methods to collect, analyse and display the data at later stages cannot make up for the bad design. The consequence is that the results can be useless for policy makers. While officials may outsource most of the steps to consultants, they should be aware of the key issues in each of the steps in order to judge the quality of consultant's work and understand survey results.

Chapter 4
Understanding the Drivers of Perception to Improve the Use of Survey Results

This chapter explains what factors drive perceptions of the quality of regulatory reform programmes (Section 1) and provides guidance to highlight these factors for a specific survey (Section 2). Policy makers will gain an understanding of the factors that drive survey results to maximise the survey's policy utility and use. This chapter draws on research on perceptions as well as on country experiences and applies those to the field of regulatory policy.

Beyond survey design and methodology, a number of factors such as trust in government, experience with front-line services or prior expectations shape responses to perception surveys at a more fundamental level. This means that the same survey results may nonetheless be driven by very different underlying factors and that without knowing what factors drive the results, policy makers cannot define appropriate policy conclusions.

The fundamental drivers of perceptions

Some drivers of perceptions that underlie survey results are directly linked to regulatory reform, implementation and communication, and hence are shaped by regulatory policies and their implementation. Others are linked to characteristics and attitudes of individuals such as general trust in government. These are less likely to change as a function of regulatory policies and communication.

Drivers of perceptions linked to regulatory reform, implementation and communication

- *"Irritation" could have a greater influence than actual costs*: An individual's sense of hassle or irritation may have a larger impact on their overall perception of regulation than its measurable costs. For example, according to the 2009 Action Programme for Reducing Administrative Burdens in the EU, "the degree to which businesses consider an information obligation to be irritating (irritation factor) is very often uncorrelated to the administrative burdens imposed" (European Commission, 2009, p. 5; see also OECD, 2010). Irritating experiences are often more memorable than those linked to benefits (UK Department for Business Innovation and Skills, 2009), especially for businesses (Russo, 2010).

- *Service quality:* Citizen and business perceptions of regulations are shaped by their experience with the front-desk staff responsible for implementing regulation. Factors of service quality include "professionalism, timeliness, staff attitude, and information" (Skinner, 2010, Slide 31). For example, participants in the Canadian CFIB Survey identified customer service issues such as being put on hold by a regulator, rude or poorly-informed agency staff, and getting more than one answer

to the same question, as a large part of the "regulatory headache" (Canadian Federation of Independent Business, 2010, p. 12).

- *Regulatory language:* Regulatory texts are usually written in very legalistic and administrative language which is difficult for citizens and businesses to understand. This may shape their perceptions of regulation towards the negative.

- *Compliance costs:* The distinction between administrative burdens and substantive costs of complying with regulations is not always clear or relevant to businesses. Administrative burden reductions may therefore not influence survey results positively, if the substantive compliance costs remain high. For instance, reducing administrative burdens by minimising information obligations of environmental regulations may not lead to more positive survey results if those regulations still require costly investments in machinery.

- *Frequency of reform:* By changing institutionalised practices, reform *per se* may create significant irritation costs, especially for businesses. Reform can make businesses uncertain of compliance requirements (KPMG LLP, 2010); the Danish Burden-Hunter Project cited government uncertainty and unpredictability as drivers of negative perception (Wissing Jensen, 2010).

- *Lack of awareness of benefits:* Businesses and citizens are unaware of the full impact of regulations in terms of costs and benefits for society. Benefits are often diffuse, whereas costs affect individual businesses and citizens more directly

- *Issue salience and visibility:* The UK Better Regulation Executive (BRE) linked contact with and understanding of regulations to a more balanced view of their costs and benefits; the BRE identified that well-informed individuals were usually more positive about regulation, "show[ing] a grasp of both benefits and costs, which can be quite sophisticated, and often with personal experience of the issues involved" (UK Department for Business Innovation and Skills, 2009, p. 69). However, bad regulation may be more visible than good regulation (FreshMinds, 2009). The majority of news stories [about regulation] was found to be negative (FreshMinds, 2009),

and may serve to mythologise regulatory burdens. Furthermore, stories of regulatory burdens are more likely to remain in the public consciousness than stories of regulatory successes. The UK Better Regulation Executive reports that "regulation seen as good appeals to common sense […] and in many instances quickly renders itself invisible as it comes to be taken for granted. Conversely, regulation seen as bad remains highly visible as it grates against what the public perceives to be fair and sensible" (FreshMinds, 2009, p. 20).

- *Government and media communications:* According to a recent study conducted in the United Kingdom, the media has the potential to influence an individual's opinion about regulations, especially if the individual does not have personal experience to draw on (UK Department for Business Innovation and Skills, 2009). The same study revealed that media reporting about regulations is mostly negative. Memorable stories of regulatory success communicated by the government can improve perceptions of regulation and emphasise that "compliance is standard" (Russo, 2010, Slide 18).

- *Involvement:* Respondents, especially business respondents, highlighted the desire for consultation at the early stages of the policy development process in several country surveys. Discussions echoed this emphasis on consultation from a governmental perspective and posited that stakeholder involvement might constitute an element of perception formation. Experience in Denmark showed that businesses responded very positively to participating in the Burden Hunters project, which aimed at "allowing business to set the agenda and be heard". It was emphasised though that continued support depends on the solutions actually developed (Wissing Jensen, 2010, Slide 4).

- *Timing:* Survey respondents may be unaware of regulatory reforms because of the time lag between reform implementation and diffusion, or because of the low visibility of reforms. Surveys need to be conducted once survey respondents are aware of reforms and can feel their effect.

Drivers of perceptions linked to respondents' characteristics and attitudes

- *Area/demographic factors:* Areas with lower average income may report more negative perceptions of regulation in general than better-off areas. For example, persons from deprived areas in the United Kingdom reported significantly lower overall satisfaction levels with their local area than their wealthier counterparts in a survey conducted by Ipsos Mori (Skinner, 2010).

- *Businesses have different perceptions from the public:* Business perceptions of regulation may be more negative than those of the general public. This may be due to the increased focus by businesses on the costs of regulation rather than on the benefits. By contrast, citizens often think of the benefits of regulation more than the cost. Furthermore, businesses have an incentive to project negative perceptions of regulatory quality in order to motivate more drastic deregulation. However, business responses are complex: business respondents balance roles as both citizen and business-person (Russo, 2010) and of course not all businesses are the same.

- *Perceptions among businesses vary:* Business perceptions often differ based on size and sector (Atkinson and Van der Zwet, 2010), as well as other factors such as number of years in business, competitive conditions, and business strategy (Carter *et al*., 2009). One reason might be that compliance costs are proportionally higher for some sectors and for smaller businesses. For example, the Business New Zealand/KPMG 2008 survey (KPMG LLP, 2008) identified a regressive effect from compliance costs; that is, smaller businesses incur higher compliance costs per employee than larger businesses. In line with this finding, the Board of Swedish Industry and Commerce for Better Regulation (NNR) states that "developments regarding burdensome and costly regulations are also of greater concern for SMEs than for larger companies" (Board of Swedish Industry and Commerce for Better Regulation, 2010, p. 19).

- *Businesses may not be sensitive to regulatory changes:* The way businesses conceptualise regulation may remain static, despite government interventions. Deregulation and administrative

burden reduction do not create competitive advantages for individual firms. Rather, the benefits are diffuse, creating gains for every firm, and thus for the overall economy. Because firms cannot gain efficiency advantages over their domestic competitors through deregulation, it may have little effect on perceptions. It may also be that because "rules and regulation are always negative, relieving it is a non-event (like the inconspicuousness of a relieved pain)" (Schippers, 2010, Slide 17).

- *Attitudes and interests:* Perceptions of regulation are sometimes irreversibly tied to fundamental attitudes and interests, such as general trust in government. Steyaert termed these 'psychographic' characteristics (Steyaert, 2010, Slide 7). For example, questions about regulation could trigger inherent beliefs about government, so that a general sense of dislike of government is automatically tied to a sense of low regulatory quality. Van de Walle (2003) writes that citizens' trust in government influences their evaluation of government performance (Van de Walle and Bouckaert, 2003).

- *Cultural differences:* Attitudes such as trust in government often have very different characteristics across nations. In the United Kingdom, for example, "the power and prevalence of what might be termed 'anti-regulation' discourses in the wider society" might serve to explain part of UK "business owners' general perceptions of employment rights, [which] often differ from their concrete experiences" (Kitching, 2006, p. 16). Business owners may see employments rights in general as a burden, and simultaneously claim positive effects on their own firm. The results of perception surveys in countries with generally negative attitudes towards the state might therefore be artificially lower compared to other countries, regardless of actual regulatory performance, due to the commonality of such sentiments as "Public services are intrinsically inefficient" (IPSOS MORI Social Research Institute, 2003, p. 30).

- *Expectations:* As expectations rise, perceptions may be lower, whether or not actual quality has changed. Expectations form a critical part of the way end-users perceive the quality of regulatory policy; Van de Walle and Bouckaert (2003, p. 2)

write that the performance of public administrations and satisfaction of its users are "not necessarily related because of the subtle interplay of reality, perception and expectations". An increase in expectations may thus stem from changes in a number of factors unrelated to actual regulatory improvement, such as consumer demand or systemic feelings about government.

- *Political changes:* Because fundamental political attitudes about government have a significant impact on perceptions, political change can bring a shift in perceptions of regulatory performance, independent of any actual changes.

How to identify the drivers of perception

Most perception surveys are informative about general trends in business and citizens' perceptions of the quality of regulations, of regulatory costs and burdens and of the level of awareness of particular regulatory reform programs. However, most survey questions are too general to provide information about the drivers of those perceptions. In order to correctly interpret survey results and to decide on appropriate policy responses, it is necessary to understand the underlying drivers of perceptions. The reasons is that the same survey result can be caused by different factors, and hence require different policy responses.

OECD countries have tested a number of both qualitative and quantitative tools to identify the drivers of perceptions underlying their survey results.

Qualitative tools

Qualitative research methods may include focus groups, open-ended survey questions, interviews and case studies. In the UK's "better regulation, better benefits survey", a qualitative research phase preceded the quantitative perception survey. Twenty-five business owners and 25 citizens from different areas were selected, following as broad a representative sample of the UK population as possible. In-depth interviews provided important insight on question formation, perception drivers, and individual experiences. For example, the study revealed that very few respondents could give a confident definition of what regulation was and that few respondents were able to tie specific

regulation back to the governing regulatory body. It also became clear that perceptions of regulation do not only vary from one individual to the next but that individuals also do not hold uniform views. For example, one respondent may perceive the smoking ban recently introduced in the United Kingdom as positive, while also perceiving health and safety regulation in general as negative (Russo, 2010).

Other countries conduct perception surveys independently from quantitative surveys. For example, in Denmark, the Burden Hunter technique relies on observations of everyday business practices, interviews, and data analysis to shed light on the day-to-day routines of the end-users of regulation. While it was developed as a stand-alone measure, it can also be used to complement and contextualise data from perception surveys and the Standard Cost Model (SCM) (see Box 4.1).

Box 4.1. Drivers of (negative) perceptions:
Insights from the Danish Burden-Hunter Project

The Danish Burden Hunter Technique aims to get a better understanding of what is driving business perceptions of government and regulations, and to develop solutions to cut red tape that businesses experience as the most irritating. Consultants visited businesses in Denmark to collect quotes, audio, and video data on businesses' day-to-day experience with regulations including interaction with public authorities responsible for regulatory matters. The following drivers of negative perceptions were identified:

1. Inflexibility

2. Lack of mutual obligation

3. Unfairness

4. Uncertainty and unpredictability

5. Pointlessness

6. Lack of respect from the public authorities for the fact that "this is my enterprise and these are my enterprise's day to day activities"

7. Lack of confidence in "my good intentions and acknowledgement of my knowledge and experience in operating a company today"

8. Complexity

9. Powerlessness and lack of clarity in authorities' roles

Further literature hints for qualitative research can be taken from the syllabi database of the "Consortium on Qualitative Research Methods", Syracuse University: *www.maxwell.syr.edu/moynihan/cqrm/Syllabi_Database*.

Quantitative analysis

Countries can choose to collect additional survey data on respondents' characteristics to control for their effect on survey results. This may include information on income, direct experience with regulation and general trust in government. It is then possible to use quantitative methods to analyse to what extent answers to regulatory questions depend on these characteristics.

For example, a key feature of Belgium's KAFKA model for perception studies is to collect information on socio-demographic, behaviouristic and psycho-graphic characteristics of the respondents as depicted in Figure 4.1. The idea behind this data collection is to understand "who answered what", i.e. whether answers to questions on regulatory burdens depend for example on the respondents' educational background or on their trust in government. The sampling method and size needs to be adjusted to ensure that there is a sufficient number of respondents with certain characteristics to draw valid conclusions, e.g. that there is a sufficient number of respondents with and without a university degree to draw general conclusions about differences in their answers (see previous chapter).

Conclusion

Perceptions, and hence survey results, are shaped by many factors, of which the actual quality of regulations is only one. For example, perceptions of the quality of regulations can be influenced by trust in government, the current economic situation, experience with front-line service, prior expectations and the content of government (and general media) communication. It is therefore necessary to look beneath survey results. In-depth questions and selected qualitative research techniques such as focus groups, case studies and in-depth interviews can prove very valuable in bringing to light the reasons for the results and drawing concrete policy conclusions from survey results.

Chapter 5
Policy Lessons for the Use of Perception Surveys for Evaluation, Diagnosis and Communication

This chapter discusses the strategies used by OECD countries in order to benefit the most from stakeholder surveys for evaluative and diagnostic purposes (Section 1) and to better communicate reforms (Section 2). It provides policy makers with policy lessons to address the complexity of perceptions and the risks entailed in the interpretation, use and communication of survey results.

Using perception surveys in regulatory policy evaluation and design

Many OECD countries run perception surveys to evaluate or inform the design of regulatory policies. In Canada, for example, the results of the survey on regulatory compliance costs are intended to help determine whether efficiency measures introduced by government are helping business save time and money and have made it easier to deal with administrative forms. In the Netherlands, the micro and macro perception surveys serve to find the answer to the question: "Are we doing the right things, and are we doing the things right?" (Atkinson and Van der Zwet, 2010, Slide 8).

However, governments cannot rely exclusively on survey results to benchmark the performance of their regulatory policy. The reason is the complexity of perceptions discussed in the last chapter: many factors can cause changes over time that are independent of changes in regulatory reform policies. In line with this, most countries involved in the OECD's work on perception surveys did not report a clearly defined standard process of using the results. Commonly, results were reported to be circulated as part of high-level reports for discussion, but it was not clear to what extent the results influence policy actions compared with other information available to government.

While there is no systematic evidence on the actual use and impact of the results of perception surveys, three policy lessons for the *use* of such surveys are particularly worth emphasizing. These are based on the experiences and insights of OECD officials and academic experts as reported at the 2010 OECD workshop on perception surveys in Istanbul:

Policy lesson 1: It is necessary to look beneath survey results.

Perceptions and hence survey results are shaped by many factors. Thus, before drawing any concrete policy conclusions, it is necessary to look beneath a survey's results in order to understand what factors are driving them. For example, two countries may run an identical survey and findings may indicate in both countries that businesses perceive an increase in administrative burdens. The identical survey results in both countries do not necessarily mean that the reasons for this perceived increase in burdens are identical. For example, in one country the negative survey results might be due to negative experiences with front-line service staff and public authorities in charge of regulatory matters, while in the other country a degradation of the economic climate led people to answer negatively. In-depth questions and qualitative research

methods prove very valuable in bringing to light the reasons for the results and drawing concrete policy conclusions.

Policy lesson 2: A comprehensive evaluation system will include different types of indicators, each revealing different information for policy evaluation.

A combination of different evaluation tools brings different pieces to the performance puzzle, as every evaluation tool has its strengths and limitations. Discrepancies in results can show the need for deeper analysis to evaluate and inform policies. For example, in many countries surveys have tended to reveal negative perceptions of the quality of regulations while in contrast more facts-based measurements have shown an improvement. As discussed in Chapter 1, this appears to apply, particularly with respect to programmes targeted at reducing administrative burdens. Table 2 illustrates this gap with an example from Sweden where the areas identified as most burdensome by the Standard Cost Model (SCM) were different from those identified as burdensome by businesses in a perception survey.

Table 5.1. Results of the regulation barometer and the SCM measurement in Sweden

Most costly areas according to SCM measurements	Most burdensome areas according to NNR Members
1. Company Law	1. Environmental Law
2. Accountancy	2. Health and Safety Legislation
3. Food Safety	3. Labour Law
4. Planning Law	4. Statutory Audits
5. Tax regulations	5. Tax regulations
6. Labour law	6. VAT
7. Consumer and Product Safety	7. Statutory action plans for equality
8. Environmental Law	8. Statistics and providing information to government

Source: Hedström, Jens (2010), "Measuring Progress in Regulatory Reform", presented at the OECD Workshop on Measuring Progress in Regulatory Reform: Perception Surveys, 21-22 June, Slide 4, available at *www.oecd.org/dataoecd/13/53/45604673.pdf*.

Along with qualitative research methods, stakeholder consultation can help to understand the discrepancies between the results on different evaluative tools and to inform reforms accordingly. For example, it might be worth testing different explanations for the gap between the SCM and the perception measurement, such as the relatively small role administrative burdens play in compliance costs or the persistence of irritation costs.

Policy lesson 3: Irritation costs and negative front-line service experiences seem to explain a significant degree of business and citizen's dissatisfaction with regulation.

Lessons learned from perception studies conducted in a number of OECD countries participating in the workshop in Istanbul 2010 seemed to suggest that irritation costs and negative front-line service experience explain a significant degree of business and citizen's dissatisfaction. Often, this can be to a greater extent than is suggested by the measurable costs of administrative burdens. Some OECD countries therefore focus on policy actions that reduce irritation costs. Of course the reasons for the same survey results can differ significantly across countries, and irritation costs may not be responsible for bad survey results in all OECD countries. Governments are therefore well advised to first understand the reasons for the results before designing appropriate policy responses (see Chapters 2, 3 and 4).

Using perception surveys for communication with stakeholders

Perception surveys can be an integral part of a two-way communication strategy with stakeholders. First, they can help to evaluate the success of the government's communication strategy by assessing the level of awareness of recent initiatives among stakeholders. Second, perception surveys can serve as a means to communicate stakeholder views on regulatory reform to the government and a discussion of the results can lead to fruitful exchanges between government and stakeholders on the case for regulatory reform.

Communicating regulatory reform to stakeholders

Perception surveys can provide information about stakeholders' awareness of regulatory reform programmes, of their awareness of changes in particular regulations and of their awareness of costs and benefits of regulations. This means that they provide important information about the effectiveness of the government's communication strategy. For example, the Dutch Macro Business Sentiment Monitor asks: "Are you familiar with the government's intention to reduce the number of laws and regulations and the resulting obligations?" and the Swedish Regulation Barometer asks: "Are you aware of the Government's better regulation programme?"

Stakeholder awareness is crucial for regulatory reform to succeed: limited awareness of changes in regulation may lead to low levels of compliance with the new regulations. Similarly, a low level of awareness of a government's regulatory reform programme may lead to limited support for it. If stakeholders are only aware of the costs of regulations to them and not of the costs and benefits for the society as a whole, they may not support a growth and welfare enhancing regulatory policy.

Box 5.1 lists a number of lessons learned in Denmark, the Netherlands and the United Kingdom to successfully communicate regulatory reform to businesses, and hence to raise awareness of government initiatives and to improve perceptions of regulatory reform through better communication.

Box 5.1. Lessons for communicating regulatory reform from Denmark, the Netherlands and the United Kingdom

The United Kingdom, Denmark and the Netherlands compiled key lessons learned in their countries for communicating regulatory reform to businesses. Concretely, they advise to:

- Focus on specific target groups and adjust the message to them;

- Create a corporate government website on regulatory reform;

- Provide companies with a question box;

- Run a media campaign with examples of changed regulations;

- Give an overview of what government does and has done to reduce burdens, presenting clear examples of burden reductions and administrative simplifications made by government;

- Have others (ambassadors and businesses itself) spread the message of burden reduction and noticeable simplification.

Communication to enterprises must be:

- *Timed* so they get the information when they need it – when they do not need it they discard it;

- *Targeted* to specific enterprise so they know the information is relevant to them;

- *Sufficient* so the enterprises do not have to seek further information.

Information taken from Atkinson, Rachel and Daphne Van der Zwet (2010), "Examples and lessons learned on Perception and Communication", presented at the OECD Workshop on Measuring Progress in Regulatory Reform: Perception Surveys, 21-22 June, Slides 5; pp. 11-13, available at *www.oecd.org/dataoecd/57/24/45640144.pdf*.

Engaging in a dialogue and learning from business and citizens

A good communications strategy is not limited to a public relation strategy. Stakeholders are not just passive receivers of government communication. Rather, their knowledge and support is crucial to a successful regulatory reform design and implementation. A good comprehensive communication strategy is a two-way strategy, involving stakeholders at every step of the regulatory reform cycle (see Box 5.2). This can include the use of perception surveys to systematically gather stakeholder feedback. Governments can also discuss the results of perception surveys with business and consumer representatives to understand what is behind the results, to identify what really bothers stakeholders, and to define priority areas for future reforms. For example, the government in Belgium discusses the results of the biannual survey on administrative burdens with businesses involved in the project.

Box 5.2. A two-way communication strategy: Involving businesses

The United Kingdom, Denmark and the Netherlands identified concrete actions that foster co-operation with business and help gather information and feedback from business on the case of regulatory reform:

- Involve stakeholders in an early stage of regulatory reform, for example by organising working panels to identify key issues for businesses;

- Listen to their stories and give feedback on what has been done to solve their problems;

- Have a complaint website; use one sender. For example, in the Netherlands, businesses are referred to the website *answersforbusiness.nl*;

- Work together with branch organisations like the Federation of Small and Medium-sized enterprises;

- Measure perceptions of businesses.

Information taken from Atkinson, Rachel and Daphne Van der Zwet (2010), "Examples and lessons learned on Perception and Communication", presented at the OECD Workshop on Measuring Progress in Regulatory Reform: Perception Surveys, 21-22 June, Slides 11-13, available at *www.oecd.org/dataoecd/57/24/45640144.pdf*.

Communicating results to stakeholders usually implies making results publicly available. Many countries do publish the results (see Table A.1 in the Annex). Some use results only for internal discussions and other governments publish them widely when they are positive.

Publishing results has the advantage of enhancing transparency and accountability, and to make a public debate possible. Some risks associated with publication are that results might be easily misinterpreted and that media may report results without taking into account the complexity of the perceptions driving those results. Survey results might be used by governments, the opposition and civil society to demonstrate the effectiveness of certain policies, criticise the government or to lobby for reforms, depending on the political agenda of those interested in the surveys. Systematic evidence on the use of perception data by different groups across a number of OECD countries is not available.

Lessons learned in some OECD countries to address these risks suggest that:

- Governments should publish the results of perception surveys along with the insights gained from qualitative studies on the factors underlying the results, the methodology used and data from other sources and indicators on the same topic.

- The design of the survey should be neutral, *i.e.* surveys should not be designed to support electoral voting intentions, political party preferences or ratings of the performance of a political party or its leaders (Turcotte, 2010).

Conclusion

Perception surveys are used for *i)* regulatory policy evaluation and design and for *ii)* communication. First, they evaluate the success of regulatory reform programmes from a user's perspective and serve as a diagnostic tool, to identify areas of concern to business and citizens to inform future regulatory reforms. Perception surveys, while useful, have their limitations. Experience suggests that there is likely to be a disparity between the perceived quality of regulations as reported by business and citizens and the measurable results of regulations. For example, in many countries surveys have tended to reveal negative perceptions of the quality of regulations while in contrast more fact-based measurements have shown an improvement. This appears to apply in particular with programmes targeted at reducing administrative burdens. A comprehensive evaluation system will therefore include different types of indicators, each revealing different information for policy evaluation. Discrepancies in results can highlight the need for deeper analysis to evaluate and inform policies.

Perception surveys are also an integral part of a two-way communication strategy with stakeholders. They can serve as a means to communicate stakeholder views to the government, and as a basis for discussion that can lead to fruitful exchanges between government and stakeholders on the case for regulatory reform. Survey results can also help to evaluate the success of the government's communication strategy by assessing stakeholders' level of awareness of recent initiatives.

Glossary

Administrative burdens/costs

The costs involved in obtaining, reading and understanding regulations, developing compliance strategies and meeting mandated reporting requirements, including data collection, processing, reporting and storage, but not including the capital costs of measures taken to comply with the regulations (see compliance costs), the general economic costs, or the costs to the public sector of administering the regulations.

Compliance costs

"All the costs of complying with regulation, with the exception of direct financial costs [e.g. administrative charges or taxes] and long-term structural consequences" (Standard Cost Model Network, 2005, p. 6). Compliance costs can be divided into "substantive compliance costs" (e.g. the costs of new machinery that has been bought to comply with new environmental standards) and "administrative costs" (e.g. the costs for reporting the installation of this new machinery to the administration).

Focus group

An interviewing technique whereby respondents are interviewed in a group setting.

Irritation (costs)

An individual's sense of hassle or irritation.

Non-respondents

All individuals or businesses from a *sample* that do not provide responses to a survey.

Question priming

"Priming occurs when prior items (primes) in a questionnaire affect subsequent items" (Van de Walle / Van Ryzin, 2011, p. 2). This means that previous questions affect responses to subsequent questions. For a concrete example, see Box 2.1.

Regulatory reform

Changes in the capacity of institutions and systems for regulatory management that improve regulatory quality, that is, enhance the performance, cost-effectiveness, or legal quality of regulation and formalities.

The term is also associated with measures targeted at a specific sector with a view to improve economic performance.

Sample

"A subset of a [target] population" (Lohr 2010, p. 3). Here synonymous with the people receiving the survey.

Sample size

"The number of sampling units which are to be included in the sample" (International Statistical Institute, 2003, p. 358). Here synonymous with the number of people receiving the survey.

Sampling error

"The error that results from taking one sample instead of examining the whole [target] population" (Lohr, 2010, p. 16).

Screening question

Questions asked in different ways in order to identify consistent respondents and meaningful responses.

Target population

"The complete collection of observations we want to study" (Lohr, 2010, p. 3). Here synonymous with the group(s) of people or businesses we would like to know more about.

Annex
Overview Table on Perception Surveys

Table A.1 provides an overview of the focus, purpose, target population and methodology used in 21 perception surveys in the regulatory field conducted in 14 OECD countries. It draws on information provided by OECD member country officials in 2010 on perception surveys in their countries. Table A.2 (available online at *www.oecd.org/regreform/measuringperformance*) provides more detailed information including survey questions, key findings and some information on the policy use of the results.

Table A.1. Overview of perception surveys in OECD countries

Country	Survey name	Responsible institutions	Target population	Last survey date / Time series	Sample size and methods used	Focus areas / purpose of survey	Website[1]/ contact/ sources of information
Australia	The Business Perceptions Survey	The Australian Taxation Office Recent surveys conducted by the Ipsos-Eureka Social Research Institute	Very micro, micro and small to medium-sized business operators	May 2009 The first survey was conducted in 2004. Since November 2006, it has been administered on a biennial basis.	1 501 respondents Computer Assisted Telephone Interviewing technique	The aim of the survey is to investigate and track businesses' satisfaction, perceptions, attitudes, understanding and awareness in relation to the Tax Office, the tax system and services provided to businesses. These include attitudes towards deliberate non-compliance.	Access full report Website
Belgium	Administrative Burdens in Belgium (2008)	Agency for Administrative Simplification (ASA) together with the Bureau Federal du Plan (BFP)	Self-employed persons and companies of different sizes and sectors	2009 The survey has been conducted on a biennial basis since 2000.	7 600 companies, stratified sample according to size and sector Postal mail and internet	Perception of administrative burdens and quality of regulation, with a particular focus on the areas taxation, environment, employment, social security and labour	Access full report in French Website

ORGANISATION FOR ECONOMIC CO-OPERATION AND DEVELOPMENT

The OECD is a unique forum where governments work together to address the economic, social and environmental challenges of globalisation. The OECD is also at the forefront of efforts to understand and to help governments respond to new developments and concerns, such as corporate governance, the information economy and the challenges of an ageing population. The Organisation provides a setting where governments can compare policy experiences, seek answers to common problems, identify good practice and work to co-ordinate domestic and international policies.

The OECD member countries are: Australia, Austria, Belgium, Canada, Chile, the Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Iceland, Ireland, Israel, Italy, Japan, Korea, Luxembourg, Mexico, the Netherlands, New Zealand, Norway, Poland, Portugal, the Slovak Republic, Slovenia, Spain, Sweden, Switzerland, Turkey, the United Kingdom and the United States. The European Union takes part in the work of the OECD.

OECD Publishing disseminates widely the results of the Organisation's statistics gathering and research on economic, social and environmental issues, as well as the conventions, guidelines and standards agreed by its members.

Measuring Regulatory Performance

A PRACTITIONER'S GUIDE TO PERCEPTION SURVEYS

This guide helps officials use perception surveys to evaluate and communicate the results of reform processes. While the guide draws on examples from the regulatory field, it is also useful for other policy areas. In non-technical language, the guide clearly explains the challenges involved in the design and use of business and citizen perception surveys – and ways to overcome them. It also helps officials get the most out of survey results, whether conducted internally or by external experts.

Contents

Chapter 1. How OECD countries use perception surveys in the regulatory policy cycle

Chapter 2. Understanding pitfalls in the design of surveys

Chapter 3. Good practices in survey design step-by-step

Chapter 4. Understanding the drivers of perception to improve the use of survey results

Chapter 5. Policy lessons for the use of perception surveys for evaluation, diagnosis and communication
